Experiments in Genetics

We have now initiated two of a series of these experiments which we hope and believe will add to the knowledge of inheritance in Orchids and have invited all of you who are interested in this phase of Orchid Culture to join us. We intend to keep a record of the results which will be eventually published when sufficient results are in and which we believe will be of distinct benefit to all of us. We did not sufficiently anticipate the great interest that would be evidenced by all of you in this project and are, therefore, still in the process of delivering the original orders received from the first two announcements. However, the more seedlings that are raised the more worthwhile the results become and we have gone ahead and planted a lot more seed from these two original crosses and are inviting all who have not as yet joined in these ventures to do so. We are asking you to report a short description of the color and form of the flowers as they bloom and other pertinent information on a questionnaire which we will supply. It is our goal now to be able to report on several thousand plants from each of these crosses.

No. 1 LH94 C Nellie Roberts 'Tyoh' (C Bow Bells x C Dowiana Aurea,

Here we have selfed the best Nellie Roberts we have bloomed out of many. A large flower with a shape similar to and equal to the best Bow Bells. The color is mauve even though one parent is white with white and yellow lip and the other is yellow with colored lip. A self cross should, according to theory, recombine the chromosomes in the resulting offspring in many different combinations. The colors expected would be mauve, white with colored lip, white, yellow, and there could be others. We are extremely well pleased with the seedlings. They are very uniform growing with Bow Bells vigor and the leaves have a very heavy substance — just as firm as cardboard. Expect delivery in November.

No. 2 LH75 Potinara Tripoli 'Tyoh' AM-AOS (BLC Ishbel x SLC Romona) x self.....

This flower has petals and sepals of a salmon-red color, lip of deep purple crimson. Good form and substance, a vigorous grower. Four different genera are involved: namely, Cattleya, Laelia, Brassavola and Sophronitis. In this self cross, the recombination of the chromosomes should result in a wide range of interesting types and some very fine flowers should result. Delivery of new orders probably not before spring 59. You may reserve seedlings and pay when ready for delivery, if you wish.

Additional Awarded and Exhibition Type Orchids

In our last offering, we listed a number of our fine Exhibition and Stud plants. Here we are naming a few additional ones. Write for our special list just out on exhibition and stud plant divisions now available.

Seed and Pollen Bank

We are taking this opportunity to announce our new seed and pollen bank. After considerable time spent in experimentation, we have been able to keep seed fresh for a number of years. We have just recently bloomed a seedling, and after seeing and evaluating the results, replanted the original seed and obtained satisfactory germination. Pollen when properly stored can, we understand, be kept viable for at least a year and perhaps for a lot longer. We plan to continue this study. We have just recently issued a separate list of seed available and invite those interested to drop us a card and we will be glad to send this offering.

Blue Ribbon Orchid Flasks

During the past year we have offered from time to time transplanted 500cc flasks of outstanding crosses. The demand for these has been substantial and, as a result, we are now offering a greater selection. One of the greatest reasons for the success is the new formula we are using when these bottles are transplanted. This results in large, husky seedlings (50 or more) ready for community pots that are very easy to grow. A few are generally ready to go into individual pots direct from the flask. In addition, we furnish complete growing instructions; our time tested method.

LW97	BLC Norman's Bay 'Ralph Wagner' AM-AOS x LC Bonanza 'Mildred Wagner' AM-AOS Outstanding crosses of the day, Glowing mauve expected, Delivery Oet. No. 2000 1000 1000 1000 1000 1000 1000 100	\$25.00

Special Values

We have many fine hybrid crosses with only a small quantity of plants available, too few to put on a listing. Hence, we are offering the following assortments at prices which represent a saving over the regular price.

Fine Hybrid Blooming Size Plants

Two \$15.00 Three \$18.75 Four \$23.00 Five \$27.50 1 plant \$8.50

May be Cattleyas, Cymbidiums, Cypripediums, Miltonias, Odontoglossums all of one genera or any combination of the above genera that you desire.

Fine Hybrid Seedlings

Four small seedlings of the above genera are offered at \$10.00. These also may be all of one genera or assorted, whichever you prefer.

We will carefully select these plants and they will all be labeled as to name or cross.

Instructions for preparing fleaks

Many who grow crchids as a hobby have expressed an interest in growing plants from seed but have deterred by the misconception that this involves difficult and intricate procedures. Many are under the impression that a special room or planting case is necessary if one is to be even moderately successful.

Actually, planting seed is a very simple procedure that can be carried out successfully on the kitchen table with simple equipment and excellent results if a little care is taken. We have planted thousands of bottles using the following method.

The first step of course is to prepare the flasks for planting. Several firms have prepared media for sale which are advertised in the AOS Bulletin from time to time. Most of those only need distilled water added.

For those who would like to prepare their own media we can recommend the Chang formula as published in the American Orchid Society Bulletin. Volume 22 - 1953 page 200. This is as follows:

12 teaspoons Fish Emulsion 56 level teaspoons sugar 9 level teaspoons agar 1 level teaspoon Peptone

I liter Distilled water (1000 cc) pH adjust to 5.0 We have had better results with this formula by substituting 150 cc of regular canned unsweatened pineapple juice for 150 cc of the Distilled water. Some of these items mentioned can of course be purchased at the grocers or local druggists, otherwise at a Selentific supply house. Your druggist an give you the address of the nearest firm in your area. We have used Difco's Bacto-Agar #0140-01 and Difco's Peptone where these two Items are called for. You will also need a package of Nitrazine paper, a bottle of Ammonia Water and an eye-dropper to use in adjusting the pH. Also, we recommend using 500 cc pyrex flasks with one hole rubber stoppers.

Will your ingredients and heat, stirring to provent sticking to the bottom of the pan. Heat until the mixture is too hot to hold your finger in without burning. It is essential to have all the materials thoroughly dissolved. The Nitrazine paper ragisters a pH of from 4.5 to 7.5. Now take a piece of this and dip an end in the solution. If pineapple juice has been used it will register 4:5 which is acid and the lowest the paper registers. The paper turns different colors depending on the degree of scidity and this is compared to a color chart on the outside of the Nitra-zine container. Now add, drop by drop, Ammonia Water testing often until the color matches the color on the chart marked 5.0. This is about as close as you can come. However 5.2 is better so if possible the slightest shade darker. If the Ammonia Water (Ammonium Hydroxide) has a strength of 28% - 30% NH3 around 20 drops should bring the pH up to this figure. It will vary depending upon the pineapple juice used and of course if the Ammonia Water is not this strong more drops will be required. Be very careful with the Ammonia and do not inhale deeply or get it in your eyes. If by chance you add too much and get the pH too high, which is easy to do the first few times, use Hydrochloric acid to bring it back down. The same procedure is followed, add the acid drop by drop testing all the time until the paper shows the Jesired hue.

We are now ready to proceed. We have enough solution to make about 7 - 500 cc flasks. Divide this evenly among the flasks and insert the rubber stoppers. Take some non absorbent cotton and using a lead pencil plug the hole in the stopper with a small single piece that can easily be removed with the fingers when we are planting the seed but still firmly plugs the hole. Out a square of aluminum foil of sufficient size to cover the stopper and mouth of the bottle and place on the flask. We are now

			• ±	•
	*			

ready to place the flasks in an autoclave or pressure cooker. Hest 15 lbs. pressure and cook for 15 minutes. Allow to roof till the prosone is gord and remove the flasks and allow to harden. This takes several hours. You are now ready to plane the seed.

Insurnctions for planting seed

It is well to aquip choself with the following items before going shead with the actual planting of the sood.

Small test tube rack l pr. rubber gloves

Several short test bubes kittsbon tongs (housewares dept)

a graduated cylinder (which measures in cubic contineters)

Half a dozen pyrex test bubes (10 co 20 co size)

A couple ordinary eye droppers that will reach to the boatom of the shore test tubes.

Bernz-O-Matic propane torch (Any hardware store handles) Package of 4" filter paper (rapid filtering)

Can of chlorinated line (Calcium Hypoplorite) Available at grocery store,

Small glass funnel so fit folded fileer paper. Distilled water (Most drug stores handle)

Items not otherwise noted may be purchased as Scientific Supply House:

Place all of the glass items in a pan with ordinary cap water and bring to a boil for goveral minucos to aberilize this includes the tongs but leave the handles on these out of the water so you can use those to remov the other items. We place the test tube rack in the even and heat to 500 degrees for several minuses to supplize.

In the meantime take one level tap, of Chlorinated Lime and place in the graduated cylinder, to this odd 55 or of water. Shake this well. New place the test tube rock on the kitchen table and remove the test tubes etc. from the pan and place in the lact. His a solution of one para closes to four parts water in a gissr. Pot on the rabber gloves and dipping your finger in this solution rat on all parts of the gloves to sterilize. Now riltered Chlorinated Time colusion. Place the seed you are about to plant in a cooked host tuce and add a shird of a test sate of this filtered solution. Now shake this tube with the seet for soveral mineres to be sure ell parts of the seed are thoroughly meistened. When you remove the grass ware from the original pan where you have sheallised it, leave two test tubes in the pan, pour out the ordainsk vasor and this time add distilled mater. Boil this for acverse minutes and then using your sterilized congs fill each sube with this wasco and place them in the test bube rack.

New back to the seci. When the seed is placed in the chiprinated kime the seed that is fertile wil. burn a golden yellow color. You can generally soes to remain in the solution for not over 5 minates. Now using your You now have the seed on the filter paper. Take one of the tubes of distilled water and cool by holding under the cold water tap allowing the water to run down the outside of the tube but being pareful not to get any in its. Now take one of your providized eye-droppers and with the cooled distilled water wash the seed from the flitter paper into one of the chort sucrilized test tubes. The entra sterilized test tubes in the rack serve

your propane torch. Take one of your flasin and remove the fail. Dip your finger in the eleven selector and eith a drop moisten the top of the support and eleten presculing from the note: New heat the neth of the

.

.

flask with the torch for a few seconds. This is to expand the dir in the flask so when you remove the sotten plug for the few seconds necessary to shoot the mixture of seed and distilled water into the flask with the eyedropper, air will be moving cut of the flack preventing any possibility of mold or bacteria from entering from the air. Now fill your eye dropper with what you think is the right amount of said and distilled waver, pull. the sotion plug, shoot the seed into the flask as rapidly as possible and immediately replace the corver plug. We advise showing an extra eye dropper of plain scerilized distilled water into the flask immediately after you have shot in the seed. This only takes are so these seconds longer and while it is not absolutely notessary the scallional liquid in the flesk allows us to distribuse the seed more evenly over the surface of the agai. The excess liquid does no harm and ass the addictional advantage of proventing the flasks from drying out too tapidly over the ensuing months. Replace the foil dover to the flask and after noting the cross on the flask you are finished, with this one. Take the next flask and repeat this procedure. Some suggest placing the planted flask in the dark until the seed germinates. However, we have not found this to be necessary, We just keep them out of the direct sunlight until they are well gorninated.

Cymbidium seed is more difficult to bandle as this seed tends to stick to glass. Here we use a piece of starillzed wire etc. and carry a blob of seed directly from the filter pager into the hole in the stapper. This is then washed into the flask with an eye dropper of starilized water.

Ones you try this method of pieceing seed you will see how simple it is. We have tought many so plant seed by just going that the stape once or at the most twice. We he have an occasional contaminated flash but a very small percentage. If you do have exclude the thing so do is review every step you have taken, retail if you have forgotten so sterilize some them or if you have conclude any the eye dropper to come surface that was not storilized. We stabilize our ghoves several times that ng the operation with the thorax. Den't open the bitter floors repicly when actual planting is underway as it is best to keep the air as quiet as possible. We make up a lot of frasks in advance. If at one time, and shed can be planted over a period of several weeks. One might worder why the spores in the cir do not seedle an one seed when it is on the filter paper or on the top of the valor standing in the test tubes. Why, we do not know, but it apparently does not. We have found most of our brouble, when we have had trouble once or bythce, has been exceed by insummarized seed. It is very difficult, if not impossible to sterilize need sufficiently if it is badly conseminated.
